

# Vitality

Marie Bisconti, Philippe Grosjean & Elise Hennebert

## Introduction

The effect of DMSO and ethanol is evaluated at concentrations from 0 up to 2% on the vitality of spermatozoa.

## DMSO

```
vit_dms0 <- readxl::read_excel("../data/Table S2.xlsx",  
  sheet = "vitality_DMSO")  
vit_dms0$donor <- as.factor(vit_dms0$donor)  
names(vit_dms0) <- c("donor", "conc", "live", "total")  
vit_dms0$live_frac <- vit_dms0$live / vit_dms0$total  
skimr::skim(vit_dms0)
```

Table 1: Data summary

Name	vit_dms0
Number of rows	25
Number of columns	5
Column type frequency:	
factor	1
numeric	4
Group variables	None

**Variable type: factor**

skim_variable	n_missing	complete_rate	ordered	n_unique	top_counts
donor	0	1	FALSE	5	1: 5, 2: 5, 3: 5, 4: 5

### Variable type: numeric

skim_variable	n_missing	complete_rate	mean	sd	p0	p25	p50	p75	p100	hist
conc	0	1	0.72	0.75	0.00	0.10	0.50	1.00	2.00

conc -0.561
optimizer (Nelder_Mead) convergence code: 0 (OK)
boundary (singular) fit: see help('isSingular')
```

We observe a singularity because correlation between slope and intercept for the random term donor is close to the boundary. Let's see if a simplified model where only the intercept depends on the donor fits better...

```
vit_dms0_m2 <- glmer(cbind(live, total - live) ~ conc + (1 | donor),
  data = vit_dms0, family = binomial(link = "logit"))

No singularities any more. We stick with this second model. This model is:

,

$$\begin{aligned} \text{live}_i &\sim \text{Binomial}(n = 1, \text{prob}_{\text{live}=1} = \hat{P}) \\ \log \left[ \frac{\hat{P}}{1 - \hat{P}} \right] &= \alpha_{j[i]} + \beta_1(\text{conc}) \\ \alpha_j &\sim N(\mu_{\alpha_j}, \sigma_{\alpha_j}^2), \text{ for donor } j = 1, \dots, J \end{aligned} \quad (1)$$

Here is a plot of this model:

```
ggplot(data = vit_dms0) +  
  geom_jitter(aes(x = conc, y = live_frac * 100, col = donor),  
    width = 0.01) +  
  geom_line(aes(x = conc, y = fitted(vit_dms0_m2) * 100, col = donor)) +  
  labs(x = "[DMSO] (%)", y = "Live sperm (%)")
```

The Z test indicates that `conc` is significantly different from zero at  $\alpha = 5\%$  (see summary of the model above). However, it is not the best test in the case of a mixed model like here. We prefer to rely on the 95% confidence interval calculated either on the profile, or via parametric bootstrap (and especially the later one):

```
confint(vit_dms0_m2, level = 0.95) # 95% CI based on profile
```

Computing profile confidence intervals ...

	2.5 %	97.5 %
.sig01	0.1446416	0.6475042
(Intercept)	2.5820574	3.2526924
conc	-0.3598545	-0.1167625

```
set.seed(7400)
# 1000x parameter bootstrap
(vit_dms0_m2_conf <- confint(vit_dms0_m2, level = 0.95,
  method = "boot", nsim = 1000L))
```

Computing bootstrap confidence intervals ...

```
45 message(s): boundary (singular) fit: see help('isSingular')
5 warning(s): Model failed to converge with max|grad| = 0.00265077 (tol = 0.002, component 1)
```

	2.5 %	97.5 %
.sig01	4.975943e-07	0.4312967
(Intercept)	2.645017e+00	3.2162631
conc	-3.691651e-01	-0.1103052

We have 1/20 of the bootstrapped models that exhibit singularities. However, 95%CI from parametric bootstraps and from profiles are not very different. So, we can trust them. Slope for `conc` is significantly different from zero at  $\alpha = 5\%$  because the 95% CI does not contain zero.

### Additional verifications

We could double-check the significance of the slope `conc` by looking at a likelihood ratio test when dropping `conc` from the model:

```
#drop1(vit_dmso_m2, scope = "conc")
vit_dmso_m3 <- glmer(cbind(live, total - live) ~ 1 + (1 | donor),
  data = vit_dmso, family = binomial(link = "logit"))
anova(vit_dmso_m2, vit_dmso_m3, refit = TRUE)
```

Data: vit\_dmso

Models:

vit\_dmso\_m3: cbind(live, total - live) ~ 1 + (1 | donor)

vit\_dmso\_m2: cbind(live, total - live) ~ conc + (1 | donor)

	npar	AIC	BIC	logLik	deviance	Chisq	Df	Pr(>Chisq)
vit_dmso_m3	2	167.99	170.43	-81.996	163.99			
vit_dmso_m2	3	155.52	159.18	-74.761	149.52	14.468	1	0.0001425 ***

---

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

The model with `conc` is significantly different at  $\alpha$  level 5% from a reference model that sets the slope `conc` = 0. There is thus a significant effect of DMSO concentration (confirmation of results obtained from 95% CI).

We also double-check convergence of the model by trying different optimisation engines (just to make sure). First, is there a singularity in the model?

```
isSingular(vit_dmso_m2)
```

```
[1] FALSE
```

... then, a report about the model convergence:

```
vit_dmso_m2_all <- allFit(vit_dmso_m2)
```

attr(,"class")
[1] "summary.allFit"

```

## Analysis of the residuals

Let's check how the residuals distribute and if there is homoscedasticity.

```

vit_dmso <- fortify.merMod(vit_dmso_m2)
ggplot(data = vit_dmso, aes(x = .fitted, y = .screid, col = donor)) +
  geom_point() +
  geom_hline(yintercept = 0) +
  labs(x = "Fitted values", y = "Pearson's residuals")

```

There is one or two extreme values, but otherwise, residuals seem rather correctly distributed. Linearity is good here.

```

ggplot(data = vit_dmso, aes(x = .fitted, y = sqrt(abs(.screid)))) +
  geom_point() +
  geom_smooth(method = "loess", formula = y ~ x) +
  geom_hline(yintercept = 0) +
  labs(x = "Fitted values", y = "(|Pearson's residuals|)^.5")

```

Homoscedasticity of the residuals seems here acceptable (the blue curve that is a loess smoothing in the data is relatively horizontal).

Note: according to Gauss-Markov theorem that indicates that linearity, random sample, non-collinearity between predictors, non-correlation between predictors and error term and homoscedasticity are the only requirements for our GLMM, we do not have to check it. Also the model is robust to departure of Normality, and none of the tests we made depend on a Normal distribution of the residuals (we said we don't trust z/t tests and replace them by likelihood ratio tests and parameterized bootstrapped confidence intervals). However, for completeness, here is the quantile-quantile plot of the residuals:

```
ggplot(data = vit_dms0, aes(sample = .scredid)) +
  geom_qq() +
  geom_qq_line() +
  labs(c = "Theoretical quantile", y = "Pearson's residuals")
```

It appears not too bad, except for one extreme value that is clearly visible here at the top. A Shapiro-Wilk test confirms Normality:

```
shapiro.test(vit_dms0$.scredid)
```

Shapiro-Wilk normality test

```
data: vit_dms0$.scredid
W = 0.98161, p-value = 0.915
```

## Predictions

The model allows to calculate the drop in vitality according to DMSO concentration from 0 to 2%. Note that an inverse logit transformation is required. Here is an example:

```
vit_dms0_slope <- c(
  ci95_min = min(vit_dms0_m2_conf["conc", ]),
  estimate = fixef(vit_dms0_m2)[["conc"]],
  ci95_max = max(vit_dms0_m2_conf["conc", ]))
vit_dms0_slope
```

```

ci95_min    estimate    ci95_max
-0.3691651 -0.2390572 -0.1103052

```

```

#saveRDS(vit_dmslo_slope, "../data/vitality_DMSO_slope.rds")

```

Let's say we want to calculate the drop in vitality for various DMSO concentrations between 0 and 2% if the vitality of a sample without DMSO is 94%. The calculation is:

```

predict_logit <- function(conc, intercept = 1, slopes) {
  slopes_mat <- matrix(slopes, nrow = 1,
    dimnames = list(NULL, names(slopes)))
  data.frame(conc = conc, -intercept +
    boot::inv.logit(boot::logit(intercept) +
    conc %*% slopes_mat))
}
dmslo_conc <- (0:20) / 10
vit_dmslo_lost <- predict_logit(dmslo_conc, 0.94, vit_dmslo_slope)
vit_dmslo_lost

```

	conc	ci95_min	estimate	ci95_max

21	2.0	-5.782342e-02	-3.334829e-02	-1.371847e-02

```
#saveRDS(vit_dms0_lost, "../data/vitality_DMSO_lost.rds")
```

This is the lost in vitality that the model predicts. Despite being significant at  $\alpha = 5\%$ , its effect is rather small because for 2% DMSO, we loose just a little bit more than 3%, with an upper bound of the 95%CI (most pessimistic value) of less than 6%.

## Ethanol

```
vit_etoH <- readxl::read_excel("../data/Table S2.xlsx",
  sheet = "vitality_EtOH")
vit_etoH$donor <- as.factor(vit_etoH$donor)
names(vit_etoH) <- c("donor", "conc", "live", "total")
vit_etoH$live_frac <- vit_etoH$live / vit_etoH$total
skimr::skim(vit_etoH)
```

Correlation of Fixed Effects:

	(Intr)
conc	-0.448

The model is:

,

$$\begin{aligned} \text{live}_i &\sim \text{Binomial}(n = 1, \text{prob}_{\text{live}=1} = \hat{P}) \\ \log \left[ \frac{\hat{P}}{1 - \hat{P}} \right] &= \alpha_{j[i]} + \beta_{1j[i]}(\text{conc}) \\ \begin{pmatrix} \alpha_j \\ \beta_{1j} \end{pmatrix} &\sim N \left( \begin{pmatrix} \mu_{\alpha_j} \\ \mu_{\beta_{1j}} \end{pmatrix}, \begin{pmatrix} \sigma_{\alpha_j}^2 & \rho_{\alpha_j \beta_{1j}} \\ \rho_{\beta_{1j} \alpha_j} & \sigma_{\beta_{1j}}^2 \end{pmatrix} \right), \text{ for donor } j = 1, \dots, J \end{aligned} \quad (2)$$

Here is a plot of this model:

```
ggplot(data = vit_eto) +  
  geom_jitter(aes(x = conc, y = live_frac * 100, col = donor),  
    width = 0.01) +  
  geom_line(aes(x = conc, y = fitted(vit_eto_m1) * 100, col = donor)) +  
  labs(x = "[ethanol] (%)", y = "Live sperm (%)")
```

Generally, slopes seem rather close to zero, suggesting no or negligible effect of the concentration in ethanol up to 2%. Data are rather widespread. Let's check if the model can be simplified in a similar way as for DMSO using a likelihood ratio test:

```
vit_etoh_m2 <- glmer(cbind(live, total - live) ~ conc + (1 | donor),
  data = vit_etoh, family = binomial(link = "logit"))
anova(vit_etoh_m1, vit_etoh_m2, refit = FALSE) # Despite the name, it is indeed a LR test
```

Data: vit\_etoh

Models:

vit\_etoh\_m2: cbind(live, total - live) ~ conc + (1 | donor)

vit\_etoh\_m1: cbind(live, total - live) ~ conc + (conc | donor)

	npars	AIC	BIC	logLik	deviance	Chisq	Df	Pr(>Chisq)
vit_etoh_m2	3	177.31	180.96	-85.654	171.31			
vit_etoh_m1	5	181.16	187.25	-85.579	171.16	0.15	2	0.9277

The likelihood ratio test does not detect significant differences between the full and simplified models at  $\alpha = 5\%$ . We could thus use the simplest vit\_etoh\_m2 model with only a shift in the slope per donor. This model is:

,

$$\begin{aligned}
& \text{live}_i \sim \text{Binomial}(n = 1, \text{prob}_{\text{live}=1} = \hat{P}) \\
& , \log \left[ \frac{\hat{P}}{1 - \hat{P}} \right] = \alpha_{j[i]} + \beta_1(\text{conc}) \\
& \alpha_j \sim N(\mu_{\alpha_j}, \sigma_{\alpha_j}^2), \text{ for donor } j = 1, \dots, J
\end{aligned} \tag{3}$$

Here is a plot of this model:

```
ggplot(data = vit_eto) +
  geom_jitter(aes(x = conc, y = live_frac * 100, col = donor),
    width = 0.01) +
  geom_line(aes(x = conc, y = fitted(vit_eto_m2) * 100, col = donor)) +
  labs(x = "[eto] (%)", y = "Live sperm (%)")
```

```
summary(vit_eto_m2)
```

The Z test indicates that conc is not significantly different from zero at  $\alpha = 5\%$ . However, it is not the best test in the case of a mixed model like here. We prefer to rely on the 95% confidence interval calculated either on the profile, or via parametric bootstrap (and especially the later one):

```
confint(vit_eto_m2, level = 0.95) # 95% CI based on profile
```

Computing profile confidence intervals ...

	2.5 %	97.5 %
.sig01	0.1522654	0.69476915
(Intercept)	2.4218361	3.13168088
conc	-0.1583188	0.09662959

```

set.seed(74588)
# 1000x parameter bootstrap
(vit_eto_h_m2_conf <- confint(vit_eto_h_m2, level = 0.95, method = "boot", nsim = 1000L))

```

Computing bootstrap confidence intervals ...

```

30 message(s): boundary (singular) fit: see help('isSingular')
1 warning(s): Model failed to converge with max|grad| = 0.00317722 (tol = 0.002, component 1)

```

		2.5 %	97.5 %
.sig01	1.566769e-05	0.4918353	
(Intercept)	2.486681e+00	3.0805498	
conc	-1.555630e-01	0.1018761	

30 fits on bootstrapped data had singularities and one failed to converge. However, 95%CI from profiles and from parametric bootstraps are close. So, we can trust them. They indicate that the slope for `conc` is not significantly different from zero at  $\alpha = 5\%$ . He, we detect no significant effect of ethanol up to 2% on the spermatozoa vitality.

### Additional verifications

We could double-check the significance of the slope `conc` by looking at a likelihood ratio test when dropping `conc` from the model:

```

#drop1(vit_eto_h_m2, scope = "conc")
vit_eto_h_m3 <- glmer(cbind(live, total - live) ~ 1 + (1 | donor),
  data = vit_eto_h, family = binomial(link = "logit"))
anova(vit_eto_h_m2, vit_eto_h_m3, refit = TRUE)

```

Data: vit\_eto\_h

Models:

vit\_eto\_h\_m3: cbind(live, total - live) ~ 1 + (1 | donor)

vit\_eto\_h\_m2: cbind(live, total - live) ~ conc + (1 | donor)

	npar	AIC	BIC	logLik	deviance	Chisq	Df	Pr(>Chisq)
vit_eto_h_m3	2	175.55	177.99	-85.775	171.55			
vit_eto_h_m2	3	177.31	180.96	-85.654	171.31	0.2426	1	0.6223

The model with `conc` is not significantly different at  $\alpha$  level 5% from a reference model that sets the slope `conc` = 0. This is in accordance with the results we observed using 95% CIs.

We also double-check convergence of the model by trying different optimisation engines (just to make sure). First, is there a singularity in the model?

```
isSingular(vit_etoh_m2)
```

```
[1] FALSE
```

... then, a report about the model convergence:

```
vit_etoh_m2_all <- allFit(vit_etoh_m2)
```

```

## Analysis of the residuals

Let's check how the residuals distribute and if there is homoscedasticity.

```

vit_etoH <- fortify.merMod(vit_etoH_m2)
ggplot(data = vit_etoH, aes(x = .fitted, y = .sresid, col = donor)) +
  geom_point() +
  geom_hline(yintercept = 0) +
  labs(x = "Fitted values", y = "Pearson's residuals")

```

There is one extreme value, but otherwise, residuals seem rather correctly distributed. Linearity is good here.

```

ggplot(data = vit_etoH, aes(x = .fitted, y = sqrt(abs(.sresid)))) +
  geom_point() +
  geom_smooth(method = "loess", formula = y ~ x) +
  geom_hline(yintercept = 0) +
  labs(x = "Fitted values", y = "(|Pearson's residuals|)^.5")

```

Homoscedasticity of the residuals seems here acceptable (the blue curve that is a loess smoothing in the data is relatively horizontal).

With the same remark as for DMSO, here is the quantile-quantile plot of the residuals:

```
ggplot(data = vit_eto, aes(sample = .screid)) +
  geom_qq() +
  geom_qq_line() +
  labs(c = "Theoretical quantiles", "Pearson's residuals")
```

It appears not too bad, except for two lower points. A Shapiro-Wilk test indicates non Normality (probably due to the two extreme values):

```
shapiro.test(vit_etoH$.scredid)
```

Shapiro-Wilk normality test

```
data: vit_etoH$.scredid  
W = 0.89958, p-value = 0.01797
```
